

SYNCHRONIZATION OF V42bis DE/COMPRESSION FOR V34/V42 MODEM RELAY METHOD AND APPARATUS

ABSTRACT

5 Method and apparatus for synchronizing two de/compression modems, e.g.
V.42bis modems, in a voice frame network, the modems each being connected with a
corresponding gateway to form a corresponding segment, are described. The method
includes terminating the physical layer at either end of the corresponding gateways;
negotiating at either gateway a physical layer and error-correcting data link layer with the
10 corresponding modem; sending from either gateway to an associated modem in response to
any poll command therefrom a not-ready message; signaling the other gateway when physical
layer and error-correcting data link layer negotiations have been completed; and when each
gateway has signaled the other that negotiations have been completed, halting the not-ready
message-sending and sending instead a ready message to a corresponding modem, whereby
15 synchronized compressed and decompressed data transmissions between the modems
commences on a reliable transport. Preferably, thereafter, and upon occurrence of a
destructive break condition or receipt at either gateway from a corresponding modem of an
initiate data transfer command, such condition or receipt is relayed from a segment where it is
detected to the other segment, thereby maintaining synchronization between the modems.
20 Preferably, the messages and commands are compliant with the ITU-T V.42 protocol.
